Abstract of the Disclose

Techniques are provided for securely managing and accelerating the delivery of data associated with remote sites. A client desires to establish secure communications with a remote site. Requests made from the client to the remote site are intercepted or forwarded to a proxy, which locates a local managing service associated with handling the requests. The local managing service acts as an intermediary between the client and the remote site and communicates securely with the client. Data associated with the client's requests is at least partially cached by the local managing service for purposes of accelerating the delivery of that data to the client.
